TITLE OF THE INVENTION

FUROPYRIDIN AND FUROPYRIMIDIN, INHIBITORS OF PI4K, FOR USE IN THE TREATMENT OF PARASITE INFECTION AND MALARIA

BACKGROUND OF THE INVENTION

Field of the Invention

The present invention relates to novel compounds having valuable properties, in particular those which can be used for the preparation of medicaments as well as methods of their use and manufacture. Said compounds are particularly useful as PI4K inhibitors and for the treatment or prevention of PI4K-related disorders such as protozoan infections like malaria and virus infections.

Description of the Related Art

Malaria represents a major global health burden with an estimated 229 million new cases and nearly 409 000 deaths in 2019, mostly affecting young children and pregnant women (World Malaria Report 2020; World Health Organization: Geneva, Switzerland, 2020.). It is a vector-borne infectious disease caused by the hematoprotozoan parasite of genus Plasmodium (Phillips, M. A. et al., Malaria.Nat. Rev. Dis. Prim. 2017, 3, 17050). According to data from the World Health Organization (WHO), Plasmodium falciparum was responsible for the vast majority of malaria related morbidity and mortality in sub-Saharan Africa.

Currently, the WHO recommends artemisinin-based combination therapy (ACT). Additionally, vector control measures are key players in relieving the malarial burden. However, reports of emerging resistance toward ACTs (Dondorp, A. M et al., Artemisinin Resistance in Plasmodium falciparum Malaria. N. Engl. J. Med. 2009, 361, 455−467) illustrate the necessity of a new generation of drugs to combat resistance and improve standard of care for millions of affected patients. In recent years, research has identified novel druggable target structures, which can affect plasmodium viability. The

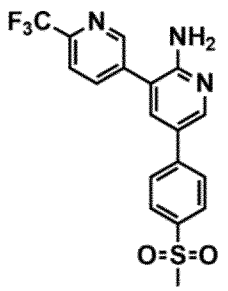
availability of a limited number of validated drug targets such as dihydrofolate reductase, cytochrome c-oxidoreductases, and hemozoin formation are a promising starting point for the development of new anti-malaria compounds and emphasizes the need to expand chemical matter toward more efficacious drugs with novel modes of action and multistage antiparasitic activity.

Within this context, Plasmodium kinases are attractive targets for new generation anti-malarials as both protein and lipid kinases are involved in key signaling pathways at various stages of the parasite lifecycle and have had some level of genetic or phenotypic validation (Arendse, L. B. et al., Plasmodium Kinases as Potential Drug Targets for Malaria: Challenges and Opportunities, ACS Infect Dis. 2021, 7(3):518-534. doi: 10.1021/acsinfecdis.0c00724).

For example, lipid kinases are important in all stages of the Plasmodium lifecycle; this includes phosphatidylinositol-4-kinase (PI4K) that catalyzes the conversion of phosphatidylinositol (PI) to phosphatidylinositol-4-phosphate (PI4P). Phosphatidylinositol 4-kinase type III beta (PI4KIIIβ) is a ubiquitous eukaryotic enzyme that phosphorylates lipids to regulate intracellular signaling and trafficking. Imidazopyrazines are known inhibitors of PI4Ks. In blood stages of malaria, imidazopyrazines block a late step in parasite development by disrupting plasma membrane ingression around developing daughter merozoites. This likely stems from altered phosphatidylinositol 4-phosphate (PI4P) pools and disrupted Rab11A-mediated membrane trafficking. (McNamara, C. W. et al., Targeting Plasmodium PI(4)K to Eliminate Malaria. Nature 2013, 504 (7479), 248−253). Plasmodium PI4K is therefore important for signal transduction and membrane trafficking and has been shown to be a validated drug target for prevention, treatment, and elimination of malaria.

Several agents were recently reported as being Plasmodium PI4K inhibitors and the 2-aminopyridine MMV390048 had reached Phase IIa clinical trials (Paquet, T. et al., Antimalarial Efficacy of MMV390048, an Inhibitor of

Plasmodium Phosphatidylinositol 4-Kinase. Sci. Transl. Med. 2017, 9 (387), 1−14) and further related compounds is shown below (PvPI4K, Pv = Plasmodium vivax).



MMV390048

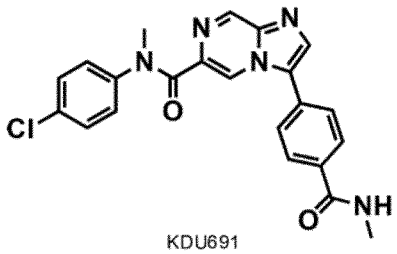
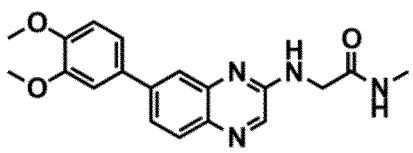
BRD73842
*Pv*PI4K - 21 nM



KDU691
*Pv*PI4K - 1.5 nM



BQR695
*Pv*PI4K - 3.5 nM

While PI4K has been identified as a useful target for protozoan infection treatment, human PI4K is also well-known to be hijacked by viruses. In particular human PI4KIIIβ, is an important host-target for viruses such as RNA viruses [PMID: 20510927; PMID: 33022924]. Therefore, PI4K inhibitors show great potential for the treatment of PI4K-related disorders such as virus or malaria infections.

While many new compounds are in development, the need for a broader pallet of effective drugs targeting PI4K is high in order to allow for combination therapies to suppress the development of resistance to single compounds. Additionally, several lead structures, which have demonstrated acceptable PI4K inhibition require high dosages in order to be effective *in vivo*. The constant development and improvement of compounds is necessary to adapt biophysical properties of compounds to increase bio-availability as well as tolerability in clinical settings. Therefore, it has been the object of the present invention to overcome the disadvantages associated with the state-of-the-art as explained above and provide alternatives with high efficacy.

The term "pharmaceutically acceptable salts or complexes" refers to salts or complexes of the compounds according to the invention. Examples of such salts include, but are not restricted, to base addition salts formed by reaction of compounds of the invention with organic or inorganic bases such as hydroxide, carbonate or bicarbonate of a metal cation such as those selected

"Pharmaceutically active compounds" refers to any compound that upon administration to the recipient, is capable of providing directly or indirectly, the activity disclosed herein. The term "indirectly" also encompasses prodrugs which may be converted to the active form of the drug via endogenous enzymes or metabolism. The prodrug is a derivative of the compounds according to the invention and presenting anti-malarial activity that has a chemically or metabolically decomposable group, and a compound that may be converted into a pharmaceutically active compound according to the invention *in vivo* by solvolysis under physiological conditions. The prodrug is converted into a compound according to the present invention by a reaction with an enzyme, gastric acid or the like under a physiological condition in the living body, e.g., by oxidation, reduction, hydrolysis or the like, each of which is carried out enzymatically. These compounds can be produced from compounds of the present invention according to well-known methods.

The term "solvates" of the compounds is taken to mean adductions of inert solvent molecules onto the compounds which form owing to their mutual attractive force. Solvates are, for example, mono- or dihydrates or alkoxides.

The term "indirectly" also encompasses metabolites of compounds according to the invention.

The term "metabolite" refers to all molecules derived from any of the compounds according to the present invention in a cell or organism, preferably mammal.

The term "malaria" includes disease and conditions related to an infection with Plasmodium.

As used herein, "treatment" and "treating" and the like generally mean obtaining a desired pharmacological and physiological effect. The effect may be prophylactic in terms of preventing or partially preventing a disease, symptom or condition thereof and/or may be therapeutic in terms of a partial or complete cure of a disease, condition, symptom or adverse effect attributed to the disease. The term "treatment" as used herein covers any treatment of a disease in a mammal, particularly a human, and includes: (a) preventing the disease from occurring in a subject which may be predisposed to the disease but has not yet been diagnosed as having it; (b) inhibiting the disease, i.e., arresting its development; or relieving the disease, i.e., causing regression of the disease and/or its symptoms or conditions. The term "effective amount" includes "prophylaxis-effective amount" as well as "treatment-effective amount".

The term "prophylaxis-effective amount" refers to a concentration of compound of this invention that is effective in inhibiting, decreasing the likelihood of the disease by malarial parasites, or preventing malarial infection or preventing the delayed onset of the disease by malarial parasites, when administered before infection, i.e., before, during and/or slightly after the exposure period to malarial parasites.

The term "prophylaxis" includes causal prophylaxis, i.e., antimalarial activity comprising preventing the pre-erythrocytic development of the parasite, suppressive prophylaxis, i.e. antimalarial activity comprising suppressing the development of the blood stage infection and terminal prophylaxis, i.e.

antimalarial activity comprising suppressing the development of intra-hepatic stage infection. This term includes primary prophylaxis (i.e. preventing initial infection) where the antimalarial compound is administered before, during and/or after the exposure period to malarial parasites and terminal prophylaxis (i.e. to prevent relapses or delayed onset of clinical symptoms of malaria) when the antimalarial compound is administered towards the end of and/or slightly after the exposure period to malarial parasites but before the clinical symptoms. Further, this term includes suppression of dormant forms of the parasite in the liver (intrahepatic or pre-erythrocytic stage) as well as the activation and elimination of dormant forms (wake-up-and-kill concept). Typically, against *P. falciparum* infections, suppressive prophylaxis is used whereas against *P. ovale*, *P. vivax* or a combination of *P. falciparum* and *P. vivax*, terminal prophylaxis is used. Suppression of dormant stages is particularly useful against *P. ovale* and *P. vivax*.

a compound of this invention or an inhibitory active metabolite or residue thereof.

A wavy line at the end of a bond line, generally appearing perpendicular to the bond line, has the same meaning as a wavy line that bisects a bond line.

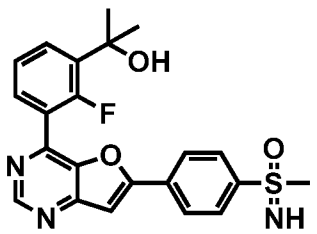
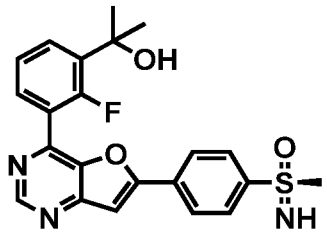
The compounds of formula (I) according to the present invention may – also depending on the nature of substituents they may bear – have one or more centers of chirality. They may accordingly occur in various enantiomeric and diastereomeric forms, as the case may be, and be in racemic or optically active form. The invention, therefore, also relates to the optically active forms, enantiomers, racemates, diastereomers, mixtures thereof in all ratios, collectively: “stereoisomers”. It may be desirable to use a specific stereoisomer, e.g. one specific enantiomer or diastereomer of a certain compound. In these cases, a compound according to the present invention obtained as a racemate or even intermediates thereof – may be separated into the stereoisomeric (enantiomeric, diastereoisomeric) compounds by chemical or physical measures known to the person skilled in the art. The compounds

of the invention which have one or more centers of chirality and which occur as racemates or as mixtures of enantiomers or diastereoisomers can for example be fractionated or resolved by methods known per se into their optically pure or enriched isomers, i.e. enantiomers or diastereomers. The separation of the compounds of the invention can take place by chromatographic methods, e.g. column separation on chiral or nonchiral phases, or by recrystallization from an optionally optically active solvent or by use of an optically active acid or base or by derivatization with an optically active reagent such as, for example, an optically active alcohol, and subsequent elimination of the radical. Another approach that may be applied to obtain one or more specific stereoisomers of a compound of the present invention in an enriched or pure form makes use of stereoselective synthetic procedures, e.g. applying starting material in a stereoisomerically enriched or pure form (for instance using the pure or enriched (R)- or (S)-enantiomer of a particular starting material bearing a chiral center) or utilizing chiral reagents or catalysts, in particular enzymes.

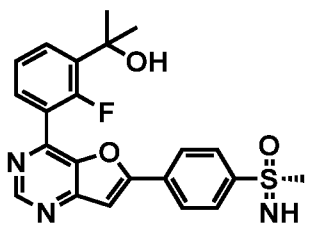
Examples of compounds according to the present invention, which have a stereogenic center are:



Racemic mixture (D203)



(*S*)-enantionmer (D209)



(*R*)-enantiomer (D210)

In this specific example the sulfur atom represents the stereocenter, in other examples of the present invention the compounds may of course have other or additional stereocenters located at a different atom e.g. at a carbon atom. As shown above, in case a compound with one or more stereocenter(s) is shown without specifying the stereoconfiguration at the stereocenter(s) this refers to a mixture of the corresponding stereoisomers.

ADMINISTRATION

The invention encompasses the administration of an compounds according to the invention or of a pharmaceutical formulation thereof, wherein said

compounds or the pharmaceutical formulation thereof is administered to an individual prior to, simultaneously or sequentially with other therapeutic regimens or co-agents useful in the treatment of malaria or viral infections (e.g., multiple drug regimens), in an effective amount. Compounds according to the present invention or the pharmaceutical formulations thereof that are administered simultaneously with said co-agents can be administered in the same or different composition(s) and by the same or different route(s) of administration.

In further embodiments, the present invention relates to a method for preventing or treating of PI4K-related disorders, wherein the method comprises the following step:

(i) providing at least one compound and/or a composition according to the present invention; and

(ii) administering an effective amount of said at least one compound or said composition to a patient in need thereof.

In a preferred embodiment said PI4K-related disorder is selected from the list of protozoan infections and viral infection, more preferably a viral infection caused by an RNA virus and most preferably malaria.

Further preferred embodiments listed above also apply to the method according to the present invention.

The invention furthermore relates to medicaments comprising at least one compound of formula (I) and/or pharmaceutically acceptable derivatives, solvates and stereoisomers thereof, including mixtures thereof in all ratios, and optionally excipients and/or adjuvants for the treatment and/or prevention of PI4K-related disorders.

Pharmaceutical compositions can be administered in the form of dosage units which comprise a predetermined amount of active ingredient per dosage unit. Such a unit can comprise, for example, 0.5 mg to 1 g, preferably 1 mg to 700

mg, particularly preferably 5 mg to 100 mg, of a compound according to the invention, depending on the condition treated, the method of administration and the age, weight and condition of the patient, or pharmaceutical formulations can be administered in the form of dosage units which comprise a predetermined amount of active ingredient per dosage unit. Preferred dosage unit formulations are those which comprise a daily dose or part-dose, as indicated above, or a corresponding fraction thereof of an active ingredient. Furthermore, pharmaceutical formulations of this type can be prepared using a process which is generally known in the pharmaceutical art.

Pharmaceutical compositions can be adapted for administration via any desired suitable method, for example by oral (including buccal or sublingual), rectal, nasal, topical (including buccal, sublingual or transdermal), vaginal or parenteral (including subcutaneous, intramuscular, intravenous or intradermal) methods. Such formulations can be prepared using all processes known in the pharmaceutical art by, for example, combining the active ingredient with the excipient(s) or adjuvant(s).

In some embodiments, the administration according to the method of the present invention takes place oral, including buccal or sublingual, rectal, nasal, topical, including buccal, sublingual or transdermal, vaginal or parenteral, including subcutaneous, intramuscular, intravenous or intradermal.

Pharmaceutical compositions adapted for oral administration can be administered as separate units, such as, for example, capsules or tablets; powders or granules; solutions or suspensions in aqueous or non-aqueous liquids; edible foams or foam foods; or oil-in-water liquid emulsions or water-in-oil liquid emulsions.

Thus, for example, in the case of oral administration in the form of a tablet or capsule, the active-ingredient component can be combined with an oral, non-toxic and pharmaceutically acceptable inert excipient, such as, for example,

ethanol, glycerol, water and the like. Powders are prepared by comminuting the compound to a suitable fine size and mixing it with a pharmaceutical excipient comminuted in a similar manner, such as, for example, an edible carbohydrate, such as, for example, starch or mannitol. A flavor, preservative, dispersant and dye may likewise be present.

Capsules are produced by preparing a powder mixture as described above and filling shaped gelatin shells therewith. Glidants and lubricants, such as, for example, highly disperse silicic acid, talc, magnesium stearate, calcium stearate or polyethylene glycol in solid form, can be added to the powder mixture before the filling operation. A disintegrant or solubilize, such as, for example, agar-agar, calcium carbonate or sodium carbonate, may likewise be added in order to improve the availability of the medicament after the capsule has been taken.

In addition, if desired or necessary, suitable binders, lubricants and disintegrants as well as dyes can likewise be incorporated into the mixture. Suitable binders include starch, gelatin, natural sugars, such as, for example, glucose or beta-lactose, sweeteners made from maize, natural and synthetic rubber, such as, for example, acacia, tragacanth or sodium alginate, carboxymethylcellulose, polyethylene glycol, waxes, and the like. The lubricants used in these dosage forms include sodium oleate, sodium stearate, magnesium stearate, sodium benzoate, sodium acetate, sodium chloride and the like. The disintegrants include, without being restricted thereto, starch, methylcellulose, agar, bentonite, xanthan gum and the like. The tablets are formulated by, for example, preparing a powder mixture, granulating or dry-pressing the mixture, adding a lubricant and a disintegrant and pressing the entire mixture to give tablets. A powder mixture is prepared by mixing the compound comminuted in a suitable manner with a diluent or a base, as described above, and optionally with a binder, such as, for example, carboxymethylcellulose, an alginate, gelatin or polyvinylpyrrolidone, a dissolution retardant, such as, for example, paraffin, an absorption accelerator,

such as, for example, a quaternary salt, and/or an absorbent, such as, for example, bentonite, kaolin or dicalcium phosphate. The powder mixture can be granulated by wetting it with a binder, such as, for example, syrup, starch paste, acacia mucilage or solutions of cellulose or polymer materials and pressing it through a sieve. As an alternative to granulation, the powder mixture can be run through a tableting machine, giving lumps of non-uniform shape, which are broken up to form granules. The granules can be lubricated by addition of stearic acid, a stearate salt, talc or mineral oil in order to prevent sticking to the tablet casting molds. The lubricated mixture is then pressed to give tablets. The compounds according to the invention can also be combined with a free-flowing inert excipient and then pressed directly to give tablets without carrying out the granulation or dry-pressing steps. A transparent or opaque protective layer consisting of a shellac sealing layer, a layer of sugar or polymer material and a gloss layer of wax may be present. Dyes can be added to these coatings in order to be able to differentiate between different dosage units.

Oral liquids, such as, for example, solution, syrups and elixirs, can be prepared in the form of dosage units so that a given quantity comprises a prespecified amount of the compound. Syrups can be prepared by dissolving the compound in an aqueous solution with a suitable flavor, while elixirs are prepared using a non-toxic alcoholic vehicle. Suspensions can be formulated by dispersion of the compound in a non-toxic vehicle. Solubilizers and emulsifiers, such as, for example, ethoxylated isostearyl alcohols and polyoxyethylene sorbitol ethers, preservatives, flavor additives, such as, for example, peppermint oil or natural sweeteners or saccharin, or other artificial sweeteners and the like, can likewise be added. The dosage unit formulations for oral administration can, if desired, be encapsulated in microcapsules. The formulation can also be prepared in such a way that the release is extended or retarded, such as, for example, by coating or embedding of particulate material in polymers, wax and the like.

The compounds of formula (I) and salts, solvates and physiologically functional derivatives thereof can also be administered in the form of liposome delivery systems, such as, for example, small unilamellar vesicles, large unilamellar vesicles and multilamellar vesicles. Liposomes can be formed from various phospholipids, such as, for example, cholesterol, stearylamine or phosphatidylcholines.

The compounds of the formula (I) and the salts, solvates and physiologically functional derivatives thereof can also be delivered using a delivery reagent such as monoclonal antibodies, nucleic acids or nanoparticles as individual carriers to which the compound molecules are coupled or enclosed. The compounds can also be coupled to soluble polymers as targeted medicament carriers. Such polymers may encompass polyvinylpyrrolidone, pyran copolymer, polyhydroxypropylmethacrylamidophenol, polyhydroxy-ethylaspartamidophenol or polyethylene oxide polylysine, substituted by palmitoyl radicals. The compounds may furthermore be coupled to a class of biodegradable polymers which are suitable for achieving controlled release of a medicament, for example polylactic acid, poly-epsilon-capro- lactone, polyhydroxybutyric acid, polyorthoesters, polyacetals, polydihy- droxypyrans, polycyanoacrylates and crosslinked or amphipathic block co- polymers of hydrogels.

Pharmaceutical compositions adapted for transdermal administration can be administered as independent plasters for extended, close contact with the epidermis of the recipient. Thus, for example, the active ingredient can be delivered from the plaster by iontophoresis, as described in general terms in Pharmaceutical Research, 3(6), 318 (1986). Pharmaceutical compounds adapted for topical administration can be formulated as ointments, creams, suspensions, lotions, powders, solutions, pastes, gels, sprays, aerosols or oils.

For the treatment of the eye or other external tissue, for example mouth and skin, the formulations are preferably applied as topical ointment or cream. In

the case of formulation to give an ointment, the active ingredient can be employed either with a paraffinic or a water-miscible cream base. Alternatively, the active ingredient can be formulated to give a cream with an oil-in-water cream base or a water-in-oil base.

Pharmaceutical compositions adapted for topical application to the eye include eye drops, in which the active ingredient is dissolved or suspended in a suitable carrier, in particular an aqueous solvent.

Pharmaceutical compositions adapted for topical application in the mouth encompass lozenges, pastilles and mouthwashes.

Pharmaceutical compositions adapted for rectal administration can be administered in the form of suppositories or enemas.

Pharmaceutical compositions adapted for nasal administration in which the carrier substance is a solid comprise a coarse powder having a particle size, for example, in the range 20-500 microns, which is administered in the manner in which snuff is taken, i.e. by rapid inhalation via the nasal passages from a container containing the powder held close to the nose. Suitable formulations for administration as nasal spray or nose drops with a liquid as carrier substance encompass active-ingredient solutions in water or oil. Pharmaceutical formulations adapted for administration by inhalation encompass finely particulate dusts or mists, which can be generated by various types of pressurized dispensers with aerosols, nebulizers or insufflators.

Pharmaceutical compositions adapted for vaginal administration can be administered as pessaries, tampons, creams, gels, pastes, foams or spray formulations.

Pharmaceutical compositions adapted for parenteral administration include aqueous and non-aqueous sterile injection solutions comprising antioxidants, buffers, bacteriostatics and solutes, by means of which the formulation is rendered isotonic with the blood of the recipient to be treated; and aqueous and non-aqueous sterile suspensions, which may comprise suspension media and thickeners. The formulations can be administered in single-dose or multidose containers, for example sealed ampoules and vials, and stored in freeze-dried (lyophilized) state, so that only the addition of the sterile carrier liquid, for example water for injection purposes, immediately before use is necessary. Injection solutions and suspensions prepared in accordance with the recipe can be prepared from sterile powders, granules and tablets.

It goes without saying that, in addition to the above particularly mentioned constituents, the compositions may also comprise other agents usual in the art with respect to the particular type of formulation; thus, for example, formulations which are suitable for oral administration may comprise flavors.

A therapeutically effective amount of a compound of the formula (I) depends on a number of factors, including, for example, the age and weight of the subjects such as animals and humans, the precise condition that requires treatment, and its severity, the nature of the formulation and the method of administration, and is ultimately determined by the treating doctor or vet. However, an effective amount of a compound according to the invention is generally in the range from 0.01 to 100 mg/kg of body weight of the recipient (mammal) per day and particularly typically in the range from 1 to 100 mg/kg of body weight per day. Thus, the actual amount per day for an adult mammal weighing 70 kg is usually between 70 and 700 mg, where this amount can be administered as a single dose per day or usually in a series of part-doses (such as, for example, two, three, four, five or six) per day, so that the total daily dose is the same. An effective amount of a salt or solvate or of a physiologically functional derivative thereof can be determined as the fraction of the effective amount of the compound according to the invention perse. It can be assumed

that similar doses are suitable for the treatment of other conditions mentioned above.

PREPARATION OF REACTANTS AND COMPOUNDS ACCORDING TO THE INVENTION

Compounds and derivatives thereof according to the present invention can be prepared from readily available starting materials using methods and procedures known to the skilled person. It will be appreciated that where typical or preferred experimental conditions (i.e. reaction temperatures, time, moles of reagents, solvents etc.) are given, other experimental conditions can also be used unless otherwise stated. Optimum reaction conditions may vary with the particular reactants or solvents used, but such conditions can be determined by the person skilled in the art, using routine optimization procedures.

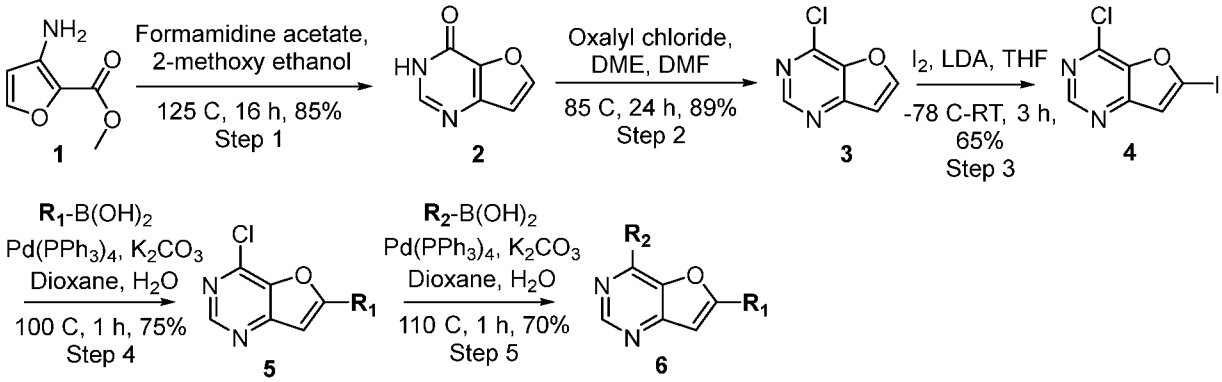
A general synthetic approach for obtaining compounds of Formula (I) is depicted in Scheme 1 below. Compounds and derivatives according to Formula (I), whereby the substituent Z is nitrogen (N), may be prepared following the synthetic pathway as outlined in Scheme 2 below.



Scheme 2: General synthesis of furo-pyrimidine core

If the above synthetic methods are not applicable to obtain furo-pyridine or furo-pyrimidine derivatives and/or necessary intermediates according to the invention, suitable methods of preparation known by a person skilled in the art should be used. In general, the synthesis pathways for any individual furo-pyridine or furo-pyrimidine derivative will depend on the specific substituents of each molecule and upon the ready availability of intermediates necessary; again, such factors being appreciated by those of ordinary skill in the art.

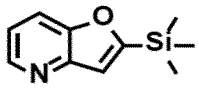
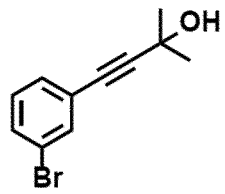
Example 1: Synthesis of reactants and compounds according to the invention following General Procedure 1

General Procedure 1: Sonogashira Cross-Coupling Reaction (GP1)



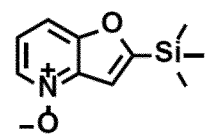
Synthesis of 2-(trimethylsilyl)furo[3,2-b]pyridine ((building block)). To a stirred solution of 2-bromo-3- hydroxypyridine (10.0 g, 57.5 mmol) in 1,4-dioxane (115 mL) were added copper(I) iodide (1.1 g, 5.6 mmol), Bis(triphenylphosphine)palladium (II) dichloride (2 g, 2.9 mmol), Triethylamine (40.1 mL, 287.4 mmol) and degassed for 15 min. Ethynyltrimethylsilane (15.9 mL, 114.9 mmol) was then added in a single portion and the reaction was heated to 55°C for 20 h. The reaction mixture was then washed through a pad of celite using ethyl acetate. It was then concentrated under reduced pressure to yield a thick brown oil as a crude product mixture. The residue was subjected to column chromatography on silica gel using hexane/ethyl acetate 9.5:0.5 v/v ratio initially and slowly increased to hexane/ethyl acetate 8:2 v/v ratio to elute 2- (trimethylsilyl)furo[3,2-b]pyridine in 90% yield as amber oil. Anal. RP-HPLC tR = 2.700 min (method 1, purity 94%); LC-MS ESI: m/z 192.1 [M+H]+ (anal. calcd for C10H14NOSi+: m/z = 192.1).



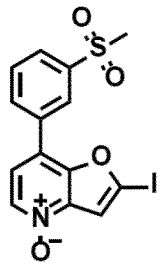
4-(3-bromophenyl)-2-methylbut-3-yn-2-ol ((building block)). According to GP1: Yield 36%. 1H NMR (300 MHz, CDCl3) δ = 7.60 (t, J = 1.7 Hz, 1H), 7.46 (ddd, J = 8.0, 2.0, 1.1 Hz, 1H), 7.40-7.34 (m, 1H), 7.23-7.15 (m, 1H), 1.64 (s, 6H); Anal. RP-HPLC tR = 1.106 min (method 2, purity 99%); LC-MS ESI: m/z = 223.0 [M-OH] + (anal. calcd for C11H11BrO+: m/z = 238.0).

<u>Example 2: Synthesis of reactants and compounds according to the invention following General Procedure 2</u>

General Procedure 2: N-Oxidation Reaction (GP2).

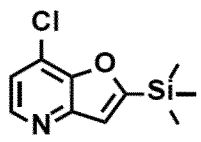


Synthesis of 2-(trimethylsilyl)furo[3,2-b]pyridine 4-oxide **(**(building block)**)**. To a stirred solution of furo[3,2- b]pyridin-2-yl(trimethyl)silane (4.2 g, 22.2 mmol) in dichloromethane (80 mL) was carefully added 3-chloroperbenzoic acid (9.6 g, 55.4 mmol) in small portions at 0 °C under nitrogen atmosphere. The reaction mixture turned into clear yellow color and after stirring at room temperature for approximately 45 min, a large amount of white precipitate had formed in the reaction mixture. The excess mCPBA was quenched by the addition of sat. NaHSO3 (100 mL). The contents of the flask were then transferred to a separating funnel and the aqueous and organic layers were separated. The aqueous layer was extracted with additional portions of dichloromethane (2 × 100 mL). The combined organic layers were then washed with Sat. NaHCO3 (2 × 150 mL) to remove the mCPBA. The organic layer was then isolated, dried over MgSO4 and finally concentrated, affording 2-(trimethylsilyl)furo[3,2-b]pyridine 4-oxide, in 93% yield as brown oil. Anal. RP-HPLC tR = 0.871 min (method 2, purity 99%); LC-MS ESI: m/z 208.1 [M+H]+ (anal. calcd for C10H14NO2Si+: m/z = 208.1).



2-iodo-7-(3-(methylsulfonyl)phenyl)furo[3,2-b]pyridine 4-oxide ((building block)). According to GP2: Yield 48%. Anal. RP-HPLC tR = 0.784 min (method 2, purity 78%); LC-MS ESI: m/z = 415.9 [M+H]+ (anal. calcd for C14H10INO4S+: m/z = 414.9).

Synthesis of 7-chloro-2-(trimethylsilyl)furo[3,2-b]pyridine ((building block)).



7-chloro-2-(trimethylsilyl)furo[3,2-b]pyridine. Trimethyl-(4-oxidofuro[3,2-b]pyridin-4-ium-2- yl)silane (0.5 g, 2.4 mmol) was added to toluene (16.1 mL). Phosphorus oxychloride (0.5 mL, 4.8 mmol) was then carefully added to the reaction mixture, which was heated to 95°C for 2 h. The excess phosphorus oxychloride was carefully quenched by the drop-wise addition of cooled (0°C) sat. NaHCO3. Once fully quenched, the reaction mixture was transferred to a separating funnel. The product was extracted using ethyl acetate (2 × 100 mL). After separating the layers, the organic layer was dried over MgSO4, filtered and concentrated, yielding a brown oil as a crude product mixture. The residue was subjected to column chromatography on silica gel using hexane/ethyl acetate 9:1 v/v ratio initially and slowly increased to hexane/ethyl acetate 6:4 v/v ratio to elute 7-chloro-2-(trimethylsilyl)furo[3,2-b]pyridine, in 44% yield as amber oil. To a solution of 7-chloro-2-(3,4,5-trimethoxyphenyl)furo[3,2-b]pyridine (100 mg, 0.27 mmol) in 1,4-dioxane (1 mL) in 10 mL microwave vial, (3-sulfamoylphenyl)boronic acid (137 mg, 0.68 mmol), tris(dibenzylideneacetone)dipalladium(0) (28.6 mg, 0.03 mmol), dicyclohexyl(2',6'-diisopropoxy-[1,1'-biphenyl]-2-yl)phosphane (43.8 mg, 0.09 mmol) and tripotassium phosphate (199 mg, 0.94 mmol) were added and degassed using N2 for 5 min. Example 19: Synthesis of furo-pyrimidine core:

Step-1: A mixture of methyl 3-aminothiophene-2-carboxylate (5 g, 0.035 mol), formamidine acetate (7.3 g, 0.070 g) and 2-methoxy ethanol (50 mL) was stirred and heated to reflux for 3 hours. The mixture was cooled to ambient temperature and water (50 ml) was added. The resultant solid was isolated, washed thoroughly with water and with diethyl ether and dried under vacuum to get furo[3,2-d]pyrimidin-4(3H)-one 2 (4.1 g, 85.06%). LCMS: Calculated for C6H6N6O2 136.11, Observed 137.1 (M+H), RT. 0.934 min, 94.28% (Max). 1H NMR (400 MHz, DMSO-d6): δ 12.60 (s, 1 H), 8.23 (d, J = 1.60 Hz, 1 H), 8.07 (s, 1 H), 6.99 (d, J = 2.00 Hz, 1 H).

Step-2: Furo[3,2-d]pyrimidin-4(3H)-one 2 (4.1 g) was taken in thionylchloride (20 ml) and DMF (0.2 ml). Stirred at reflux for 5 h. After the completion of the reaction, the reaction mixture was concentrated to remove thionylchloride, was added water, extracted using dichloromethane and dried with anhydrous sodium sulphate. After concentrated under vacuum, trituration was carried out with hexane to get 4-chlorofuro[3,2-d]pyrimidine 3 (4.1 g, 89.1%). LCMS: Calculated for C6H3ClN2O 154.55, Observed 155.1 (M+H), RT. 1.41 min, 97.42% (Max). 1H NMR (400 MHz, DMSO-d6): δ 8.92 (s, 1 H), 8.68 (d, J = 2.40 Hz, 1 H), 7.40 (d, J = 2.00 Hz, 1 H).

Step-3: To a stirred solution of 4-chlorofuro[3,2-d]pyrimidine 3 (2 g, 0.013 mol) in THF at -78°C, was added dropwise n-butyl lithium1.6 M solution in THF (12.1 ml, 0.019 mol) over a period of 15 minutes. After 2h stirring at -78 °C, was added ICl (1.01 ml, 0.019 mol) dropwise and allowed to stir at room temperature for 30 minutes. The reaction mixture is poured into water and extracted three times with ethyl acetate. The combined organic phases are washed with 10% sodiumthiosulphate solution, dried over sodium sulphate and after filtration, dried under reduced pressure. The solid obtained was washed with diethyl ether and dried to get 4-chloro- 6-iodofuro[3,2-d]pyrimidine 4 (2 g, 55.2%) as reddish orange solid. LCMS: Calculated for C6H2ClIN2O 280.45, Observed 280.9 (M+H), RT. 1.94 min, 95.31% (Max). 1H NMR (400 MHz, DMSO-d6): δ 8.85 (s, 1 H), 7.72 (s, 1 H).

General procedure for step 4:

To a stirred solution of 4-chloro-6-iodofuro[3,2-d]pyrimidine (0.285 mmol), R1-B(OH)2 (67.0 mg, 0.285 mmol) in 1,4-Dioxane (3 ml) and Water (1.00 ml) and added K2CO3 (0.571 mmol). The reaction mixture was then degassed for 5 min followed by addition of Pd(PPh3)4 (0.029 mmol). The reaction mixture was stirred for about 3h at 90^0C. The solvent was evaporated to get compound 5 as crude mixture which was taken as is for next step.

These data illustrate the potency of compounds according to the present invention in inhibiting growth of P. falciparum and underline the usefulness as anti-malaria drugs.

Example 21

Data presented in example 20 indicates a substantial impact of the compounds according to the present invention on growth of plasmodia. In order to further examine the underlying mechanisms responsible for inhibition of growth, the compounds were tested for inhibitory properties of plasmodium PI4K, a recently identified drug target for anti-malaria medication.

In order to test the impact of the compounds according to the present invention, *in vitro* assays were performed analyzing concentrations at which PI4K is inhibited. IC_{50} measurements were recorded.

The lipid kinase reaction is performed by incubating lipid substrate (PI:3PS or PIP2:3PS) with a recombinant enzyme and ATP, and the kinase activity is measured using the ADP-Glo™ Kinase Assay. First, the kinase reaction is terminated, and any ATP remaining after the reaction is depleted, leaving only ADP. Then the Kinase Detection Reagent is added to convert ADP to ATP, which is used in a coupled luciferin/luciferase reaction. The luminescent output is measured and is correlated with kinase activity. The assays can be performed in 96- or 384-well plates and can be used for enzyme characterization, inhibitor screening or compound profiling. Results measuring the effect of compounds on P. vivax PI4K are reported in table 2

These data illustrate the potency of compounds according to the present invention in inhibiting PfPI4K and provide an explanation for the discovered plasmodium growth inhibition as described in example 20.

Example 22

To further test the impact of compounds according to the present invention on human PI4Kβ, HuPI4Kβ (human PI4Kβ) inhibition was tested for selected compounds and contrasted with the results for inhibiting PfNF54 strains as described in example 20.

As illustrated in table 3, several compounds showed high potency to inhibit human PI4K in addition to plasmodium derived protein. However, some compounds, in particular comprising a furo-pyrimidine core structure showed low inhibitory properties in regard to human-derived PI4K, while strongly inhibiting plasmodia growth.

Example 23

Further compounds according to the present invention have been tested for growth inhibition of NF54 strains in order to evaluate the concentration required to reduce Plasmodium viability.

H3D - *In vitro* antiplasmodial activity

Test samples were screened for in vitro antiplasmodial activity against a chloroquine sensitive (CQS) strain (NF54) of the malaria parasite P. falciparum. Continuous in vitro cultures of asexual erythrocyte stages of P. falciparum were maintained using a modified version of the method of Trager and Jensen (1976).1 Quantitative assessment of antiplasmodial activity in vitro was determined via the parasite lactate dehydrogenase assay using a modified method described by Makler (1993). The test samples were tested in triplicate on two separate occasions. Further dilutions were prepared in complete medium on the day of the experiment. Samples were tested as a suspension if not completely dissolved. Chloroquine and artesunate were used as reference drugs.

A full dose-response were performed starting at a concentration of 3000 nM, which is then serially diluted 2-fold in complete medium to give 10 concentrations; with the lowest concentration being approximately 6 nM. The same dilution techniques were used for all samples. References were tested at a starting concentration of 1000 ng/mL. The highest concentration of solvent to which the parasites were exposed has no measurable effect on the parasite viability (data not shown).

***In vitro P. vivax* liver-stage Assay**

Compound efficacy against *P. vivax* liver-stage schizonts and hypnozoites is evaluated in infected primary human hepatocytes (PHHs). Compound screening is performed in 384-well plates, in a 12-point dose response, from 50 µM. All compounds are tested in radical cure mode (RCM).

PHHs are seeded onto 384-well plates two days prior to *P. vivax* sporozoite infection. In RCM, compounds are added to the culture for three days, from day 5 post infection, in duplicate wells. Nigericin and a PI4K inhibitor (KDU691) are used as positive controls in each assay, while solvent (DMSO) without

added compound serves as a negative control. Daily medium changes are performed, and the culture is fixed on day twelve post infection to ensure complete parasite clearance. Fixed cells are permeabilized and stained with an anti-UIS4 primary antibody and a fluorescent secondary antibody. Liver-stage schizonts and hypnozoites are then quantified by High Content Imaging.
